

Bug - 2 : Unnecessary Thread.sleep()

File : TaskController.java , line 36-42

while going through the controller, I found a Thread.sleep() which was being used for something called query complexity estimation.

The code was calculating the sleep time from the query length. Because of this, an empty query could make the server sleep for around 1 second, and shorter queries caused more delay.

This does not make sense because the sleep was not doing any actual work. It was just blocking the thread handling the request.

fix :-

I removed the Thread.sleep() code
I also replaced the System.out.println()

with the proper logger and
added validation for page and
page size.

The main reason for removing it
is that a request should not keep
a server thread blocked for no
useful reason.
If many requests come at the same
time, this can make the server
slow unnecessarily.
